From discrete to continuous models in evolutionary dynamics

Fabio A. C. C. Chalub Universidade Nova de Lisboa, Portugal

We study the large population limit of the Moran and Wright-Fisher processes, under the assumption of weak-selection, and for different scalings. Depending on the particular choice of scalings, we obtain a continuous model that may highlight the genetic-drift (neutral evolution) or natural selection; for one precise scaling, both effects are present. For the scalings that take the genetic-drift into account, the continuous model is given by a singular diffusion equation, together with two conservation laws that are already present at the discrete level. For scalings that take into account only natural selection, we obtain a hyperbolic singular equation that embeds the Replicator Dynamics and satisfies only one conservation law. The derivation is made in two steps:a formal one, where the candidate limit model is obtained, and a rigorousone, where convergence of the probability density is proved. Additional results on the fixation probabilities are also presented.
